

ARRANGEMENT COMPRISING A MICROPROCESSOR, A DEMAGNETIZATION  
CIRCUIT AND A SWITCHED MODE POWER SUPPLY, AND A DISPLAY UNIT  
COMPRISING A RESPECTIVE ARRANGEMENT

5

FIELD OF THE INVENTION

The invention relates to an arrangement comprising a  
microprocessor, a demagnetization circuit and a switched  
mode power supply operating in a normal mode and in a low  
10 power mode, e.g. a standby mode. The low power mode is in  
particular a burst mode being controlled by the  
microprocessor. Arrangements of this type are used for  
example in display units like television sets and computer  
monitors.

15

TECHNICAL BACKGROUND

Switched mode power supplies used in consumer electronics  
appliances usually have a low power mode, a so called  
20 standby mode, in which the essential circuits of the  
appliance are switched off, and only a few circuits, for  
example a microprocessor and a remote control receiver, are  
operating. To keep the power consumption in the standby mode  
as low as possible, it is known to use in the low power mode  
25 a so-called burst mode, in which the switching transistor is  
turned off regularly for defined time intervals.

For example, the switched mode power supply is switched off  
and on with a frequency of 100 Hz, in which during a short  
30 on phase the switching transistor operates at a switching  
frequency of 20 kHz, for transferring energy from the  
primary side to the secondary side of the switched mode  
power supply. Via the ratio between the on phase and the off  
phase the output power of the power supply can be  
35 controlled. During the on phase, the switching parameters  
for the switching transistor can be kept within a safe  
range. Switched mode power supplies with a burst mode are  
known for example from EP-A-0 386 989 and DE-A-195 18 863.

US 6,434,030 discloses a circuit arrangement with a switched mode power supply, in which a low power burst mode is controlled by a microprocessor. An output of the microprocessor is coupled to the control loop of the switched mode power supply, and when the arrangement is switched to the standby mode, the microprocessor applies a square wave signal with a given duty factor to the control loop. With an off signal from the microprocessor, the power supply is disabled via the control loop, and with an on signal, the power supply is enabled for a short on phase, in which the switching transistor of the switched mode power supply is operating with a regular switching frequency.

Television sets and computer monitors having a cathode ray picture tube (CRT) as a display means comprise usually a demagnetization circuit for demagnetizing the picture tube in regular intervals, for example when the appliance is switched on. For the demagnetization, also known as degaussing, a time period of about 1,5 seconds is used, in which a magnetic field is applied to the picture tube in a known manner. Generally, the demagnetization circuit in a television set operates independently from the microprocessor, but microprocessor-controlled demagnetization circuits are known also.

#### SUMMARY OF THE INVENTION

According to the invention, the arrangement comprises a microprocessor, a demagnetization circuit and a switched mode power supply operating in a normal mode and in a low power mode. The microprocessor is coupled via one output to the switched mode power supply for controlling the low power mode and to the demagnetization circuit for controlling a respective operation. The output of the microprocessor is in particular arranged as a single pin, for providing the signals to the switched mode power supply and to the demagnetization circuit via the same line.

The inventor has recognized that one output pin of the microprocessor is sufficient for controlling the low power mode, in particular a low power burst mode, as well as for the demagnetization circuit, because the respective control signals do not occur at the same time. There is only one requirement, which should be taken into account: the signal for the low power mode should not be coupled to the demagnetization circuit during the low power mode. This can be realized in a preferred embodiment by controlling the signal coupled to the demagnetization circuit by a power on-indicative signal, which blocks the signal from the microprocessor to the demagnetization circuit during the low power mode, and which allows the signal from the microprocessor to pass during the normal mode. This can be arranged for example via an AND gate, to which inputs the signal from the microprocessor and the power on-indicative signal are coupled. The power on-indicative signal can be for example a supply voltage, which is provided by the switched mode power supply during the on mode, and which is switched off during the low power mode.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The invention will be explained now in more detail with regard to schematic drawings, which show:

- Fig. 1 a switched mode power supply, to which an output of a microprocessor is coupled,
- Fig. 2 an arrangement for controlling a switched mode power supply and a demagnetization circuit,
- Fig. 3 a timing diagram showing operation modes of a display unit, and
- Fig. 4 a circuit for operating a demagnetization circuit.

#### DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The switched-mode power supply shown in Figure 1 operates on the flyback-converter principle and comprises an input connected to a mains voltage UN, which is converted by means of a rectifier G1 and a capacitor 3 to a smoothed DC voltage U1. The switched-mode power supply comprises a transformer Tr with a primary winding W1 coupled to the voltage U1 and connected in series with a switching transistor T1. In this embodiment, as a driver stage for the switching transistor T1 an integrated circuit 7 is used, although other solutions, with discrete transistor stages operating both in free-running and synchronized fashion, are also possible.

A resistor 8 connected to the voltage U1 is used to enable the switched-mode power supply to start up. During operation, the switched-mode power supply is itself supplied with voltage by means of an auxiliary winding W4, a diode 12, a capacitor 9 and a resistor 10. The switching transistor T1 is operated by the integrated circuit 7, for example using a square-wave signal 6 at a frequency usually higher than 16 kHz.

The switched-mode power supply uses secondary windings W2 and W3 of the transformer Tr to generate output voltages U2 and U3, which are smoothed by rectifiers G2, G3 and capacitors 17, 18. The output voltages U2 and U3 are stabilized by a control loop, the control loop being connected to the output voltage U3 in this embodiment. The control loop is represented in this embodiment in simplified form by a resistor 14 and an optocoupler 13, for transmitting a feedback signal to a control input 1 of the integrated circuit 7.

To the control loop an output 19 of a microprocessor 16 is coupled in simplified form, via a resistor 15. The microprocessor 16 uses in particular a digital signal, for example a CMOS signal, to start the burst mode and the

normal mode of the switched-mode power supply via output 19. For example, when the output 19 is "high", then the control loop is enabled and the switched mode power supply is in a normal mode in which the output voltages U2 and U3 are regulated via the control loop. When the output 19 provides a "low" signal, then the control loop is coupled to a low potential, and the switched mode power supply therefore disabled.

10 A circuit for coupling an output of a microprocessor to a control loop of a switched mode power supply is shown and explained in more detail in US 6,434,030. In this reference, the microprocessor generates in particular a burst mode operation in the standby mode of the switched mode power supply. In this operating mode, the standby losses of the switched mode power supply can be kept very low.

According to the invention, the output 19 is also coupled to a demagnetization circuit for providing a demagnetization of a picture tube, for example for a picture tube of a television set or a computer monitor. The arrangement comprises therefore a logical gate 23, for example an AND gate, to which inputs an operating voltage U4 and the output 19 of the microprocessor 16 is coupled. The output 19 of the microprocessor 16 is in particular a single pin for providing a signal U<sub>c</sub>, which contains the information for controlling the low power mode as well as for controlling the demagnetization circuit.

30 The operation of the demagnetization circuit is shown in more detail in figure 2. The signal U<sub>c</sub> from the output 19 is coupled to a burst circuit 21, for example to the optocoupler 13 of the control loop of a switched mode power supply as shown in Fig. 1, and coupled to a demagnetization circuit 22 via a logical gate 23, for filtering the signal from output 19 with a power on indicative signal. The gate

23 provides an AND operation, and the power on indicative signal is for example a supply voltage U4 only present in the normal mode of the switched mode power supply, for allowing the signal from the output 19 to pass to the  
5 demagnetization circuit 22 only in normal mode. The logic gate 23 is in particular an AND gate, as shown in figure 4.

Figure 3 shows in more detail the signal U<sub>c</sub> from output 19, for controlling the burst circuit 21 and the demagnetization  
10 circuit 22. In a first time interval T<sub>1</sub> - T<sub>2</sub> the power supply is in a low power standby burst mode, being controlled by the control signal U<sub>c</sub>. In this embodiment, when the control signal U<sub>c</sub> is "high", the switched mode power supply is off, and when U<sub>c</sub> is "low", the switched mode  
15 power supply is operating and regulated by output voltage U<sub>3</sub>. For generating the burst mode during time interval T<sub>1</sub> - T<sub>2</sub>, the control signal U<sub>c</sub> is a periodic square wave signal with short time periods, in which the voltage U<sub>c</sub> is "low". The pulse width ratio is close to 1, for a low power  
20 consumption of the switched mode power supply. Preferred values are for example a pulse width ratio with "high" = 95 % and "low" = 5 %.

The circuit arrangement as described is arranged for example  
25 within a television set. At time T<sub>2</sub> a user switches the television set on, and the switched mode power supply therefore switches to the normal mode for supplying all circuits of the television set with operating voltages. The signal U<sub>c</sub> from output 19 is then kept "high" for a time  
30 interval T<sub>2</sub> - T<sub>3</sub>, for providing a demagnetization of the picture tube of the television set. The interval T<sub>2</sub> - T<sub>3</sub> has in particular a duration of about 0,5 sec to 3 sec, for example 1,5 sec. Because after time T<sub>2</sub> already a power on indicative signal is present at the second input of gate 23,  
35 the output of gate 23 is high for enabling the

demagnetization circuit 22. A demagnetization circuit for a picture tube is known for example from DE-A-3830931.

After time T3 the signal Uc switches to "low" for disabling  
5 the demagnetization circuit 22. This is a preferred mode during normal operation of a television set, because then the power consumption of the demagnetization circuit 22 is zero. After time T3, the deflection of the television set is starting and the picture appears on the picture tube.

10

A preferred embodiment for coupling the output 19 of the microprocessor to a demagnetization circuit 22 is shown in figure 4. The demagnetization circuit 22 comprises a relay 25, via which the demagnetization coils (not shown) of the  
15 demagnetization circuit 22 are operated. The control signal Uc and the power on indicative signal U4 are applied to an AND gate 24. The AND gate 24 and the relay 25 are supplied with an operating voltage U5, which is present during normal mode as well as in standby mode. As explained, during the  
20 time interval T2 - T3 both inputs of the AND gate 24 are "high", and then the output of AND gate 24 is also "high", therefore switching through a transistor T2, which controls the operation of the relay 25.

25 The power on indicative signal U4 can be any signal being "low" during a low power standby mode and "high" during a normal mode. With the signal U4 it is therefore possible to disable the demagnetization circuit 25 during the low power mode, which is particularly important when a low power burst  
30 mode is used, because during the time interval T1 - T2 the demagnetization circuit would be operated by the square wave signal Uc. The relay 25 would then switch on and off with a comparatively high frequency, which would wear out the relay 25 and would lead to additional power losses in the standby  
35 mode.

The present invention is not limited to the embodiment as shown and described with regard to the figures, and various modifications come possible for a person skilled in the art without departing from the scope of the invention. For  
5 example, the invention is useable for all appliances comprising a demagnetization circuit. As the "high " signals also any other logical "enable" signals may be used. In the embodiment shown in Figure 1, mains isolation is provided by the transformer Tr and the optocoupler 13. Other embodiments  
10 without mains isolation, for example battery-powered devices, are also possible.
